

Mandibulæ cymbiolatæ, antrorsum sensim angustiores, processu masticatorio breviori subhamato, margine masticatorio singula serie denticulorum armato. Lingua elongata, compressa, serie dentium unica ; dentes arcuati, cruribus angustis, acie cuspide prominulo et utrinque denticulis compluribus. Penis inermis.

The genus *Fiona* differs from all the other *Æolidiadæ* in having a proper branchia attached to the inner side of the dorsal papillæ.

A few species have been described, all pelagic in habit, which do not markedly differ from each other, and may eventually prove to belong to one circumæquatorial cosmopolitan form.

Three specimens of this species were captured on the surface in the north-west Pacific, on June 29th, 1875, and were preserved in picric acid.

The three specimens, no doubt somewhat contracted, were about the same size ; the largest measured about 13 mm. in length, 4 mm. in breadth, and 4·5 mm. in height, the length of the tail was 4 mm.

The structure of the central nervous system was quite typical, but the otocysts could not be detected.

The *bulbus pharyngeus* in the two specimens which I examined measured 2·75 and 3 mm. in length. The *radula* contained 15 to 16 series of teeth and 6 to 9 loose teeth
